

Stabilizer Compositions for Halogen Containing Polymers

The instant invention relates to a composition and process for the stabilization of halogen containing polymer slurries, in particular polyvinylchloride (PVC). The composition comprises a halogen containing polymer in the form of an aqueous suspension or emulsion, a partially hindered phenolic antioxidant and selected sulfur containing antioxidants, which are both solid at 20° C. A further aspect of the invention is the use of specific antioxidant mixtures for the stabilization of halogen containing polymer suspensions or emulsions, in particular PVC.

The thermal stability of halogen containing polymers, such as PVC, is relatively low compared to many other polymers. Because of its otherwise good overall properties, its versatility, and cost effectiveness, it is nevertheless an extremely favorable material. However, it can only be used, if it is well stabilized against degradation induced by heat, light, mechanical stress, etc. Protection against thermal degradation is especially important.

Protection of PVC compounds and end articles against thermal degradation can be achieved by so-called "heat stabilizers" which are mostly based on metal salts of organic molecules (e.g. metal soaps), as extensively described in the literature (for example H. Zweifel, Handbook of Plastic Additives, 5th edition, Hanser, 2001, pages 427-483).

However, these heat stabilizers can only be added at the compounding stage. This means, that the halogen containing polymer resin after polymerization remains unprotected during the monomer stripping and drying process. Damages occurring at this stage lower the thermal stability of the resin and of the corresponding compounds and end articles.

To improve the heat stability during the compounding stage EP 0 849 314 suggests adding in addition to a Zn carboxylate a phenolic antioxidant and a thiodipropionic acid ester.

The additional use of phenolic antioxidants and thiodipropionic acid esters with conventional PVC stabilizers during the compounding stage, is also described in GB 1 001 344.

In the case of PVC sterically fully or partially hindered phenolic antioxidants may already be added to the reaction mixture. Sometimes small amounts of fully hindered phenolic antioxidants are added at the beginning of the polymerization and often fully or partially

- 2 -

hindered phenolic antioxidants are added towards the end of the polymerization. The thermal stability of the PVC resin, and also of the resulting PVC compound is thereby improved, however, not to a completely satisfactory level.

- 5 It has now been found that combinations of partially hindered phenolic antioxidants with thioethers or thioether-esters, added to the halogen containing polymer reaction mixture, which is in the form of an aqueous suspension or emulsion, preferably towards the end of the reaction, greatly improve the thermal stability of the halogen containing polymer and the resulting polymer compound, compared to the current state of the art.

10

Additional stabilizers may then be added also during the compounding stage.

For example the halogen containing polymer obtained, in particular the virgin PVC resin, undergoes much less dehydrochlorination (loss of chlorine from the PVC) and discoloration
 15 upon thermal treatment than conventionally stabilized PVC.

- 25 Compounds of the zeolite series (alkali metal aluminosilicates or alkaline earth metal aluminosilicates) can be described by the general formula (IV)

wherein n is the charge of cation M;

M is an element of the first or second main group of the Periodic Table, such as Li, Na, K,

30 Mg, Ca, Sr or Ba, or Zn,

y:x is a number from 0.8 to 15, preferably from 0.8 to 1.2; and

w is a number from 0 to 300, preferably from 0.5 to 30.

30

It is preferred to use zeolite P types of formula

$\text{M}_2\text{O} \cdot \text{Al}_2\text{O}_3 \cdot x\text{SiO}_2 \cdot y\text{H}_2\text{O}$ (IVa), wherein x is 2 to 5, and y is 3.5 to 10, and M is an alkali metal atom and, very particularly preferably, zeolite MAP of formula IVa, wherein x is 2 and y is 3.5

to 10. Preferred is zeolite Na-P, i.e. M is Na. This zeolite is usually obtained in the variants Na-P-1, NaP-2 and Na-P-3, which differ from each other in their cubical, tetragonal or orthorhombic structure (R.M.Barrer, B.M.Munday, J.Chem.Soc. A 1971, 2909-14). The above-mentioned literature also describes the preparation of zeolite P-1 and P-2. According to this literature, zeolite P-3 is very rare and is therefore hardly of any practical interest. The structure of zeolite P-1 corresponds to the gismondite structure known from the above Atlas of Zeolite Structures. The more recent literature (EP-A-384 070) makes a difference between the cubical (zeolite B or P_C) and the tetragonal (zeolite P₁) zeolite of the P type. It also mentions newer zeolites of the P type having Si:Al ratio of less than 1.07:1. These zeolites are called MAP or MA-P for "maximum aluminium P". Depending on the method of preparation, zeolite P can contain minor amounts of other zeolites. A very pure zeolite P is described in WO-A-94/26662.

Within the scope of this invention, it is also possible to use those finely particulate water-insoluble sodium aluminosilicates which were precipitated and crystallised in the presence of water-soluble inorganic or organic dispersants. These may be added to the reaction mixture in any manner before or during precipitation or crystallisation

Sodium zeolite A, sodium zeolite P, sodium zeolite X and sodium zeolite Y are particularly preferred.

The hydrotalcites and zeolites can also be naturally occurring minerals or synthetically obtained compounds.

The hydrotalcites and/or zeolites can be used in amounts of e.g. 0.1 to 50, conveniently of 0.1 to 10 and, preferably, of 0.1 to 5, parts by weight, based on 100 parts by weight of halogen-containing polymer.

Typical examples of naturally occurring alumo salt compounds are indigirite, tunisite, alumohydrocalcite, para-alumohydrocalcite, strontiodresserite and hydrostrontio-

5 dresserite. Other examples of alumo salt compounds are :

$\{([Mg_{0.2}Na_{0.6}]_2O).(Al_2O_3).(CO_2)_2.4.1H_2O\}$,

$\{([Mg_{0.2}Na_{0.6}]_2O).(Al_2O_3).(CO_2)_2.4.3H_2O\}$ and

$\{([Mg_{0.3}Na_{0.4}]_2O).(Al_2O_3).(CO_2)_2.2.4.9H_2O\}$.

The mixed alumosalt compounds can be obtained by methods known per se by cation
15 exchange, preferably from the alkali metal alumo salt compounds or by combination precipitation (see, for example, US 5 055 284).

The definitions, preferences and optional additives given above, apply also for the process of polymerization.

15 For example PVC can be produced from vinyl chloride monomer (VCM) by three different processes. The most widely used is the suspension type polymerization, which accounts for approximately 80-85%. Droplets of liquid vinyl chloride are dispersed in water using a protective colloid in a pressurized agitated reactor. Polymerization occurs inside the droplets as a result of the use of an oil-soluble initiator. The product is in the form of 100-150 μ m

diameter porous grains. Another process is the emulsion route, in which the monomer is dispersed in water, using agitation and powerful surfactants and the polymerization is carried out in the aqueous phase, using a water soluble initiator. The polymerization product is in the form of an aqueous latex dispersion of PVC particles 0.1-2.0 μm in diameter. These are spray-dried to form larger agglomerates, which are milled before being dispersed in solvents and plasticizers to give plastisols, used in a variety of spreading and dipping applications. The third route is bulk or mass polymerization. As the name implies the polymerization is carried out in vinyl chloride (VCM) in the absence of water. A review of the manufacturing of PVC is for example described in Encyclopedia of Polymer Science and Engineering, second edition, vol. 17, pages 295-376.

The components b) and c) can be added during the polymerization reaction or after the reaction is completed.

With regard to vinyl chloride polymerization, the overwhelming amount of polyvinyl chloride is prepared by suspension polymerization. In this process, the vinyl chloride monomer and an initiator are dispersed by agitation into a water phase at proper temperature and pressure. Suspending agents such as methyl or ethyl cellulose, gelatin, polyvinyl alcohol or other water-soluble polymers are utilized to stabilize the suspension during the polymerization reaction. Unreacted VCM is removed by a vacuum stripping process. The fine granules of polymer in the form of a slurry are discharged from the reactor and centrifuged or filtered to remove the water. Thorough washing and drying of the polymer to remove traces of the suspension stabilizer and the reaction medium conclude the procedure.

Toward the end of the polymerization cycle the pressure in the system begins to drop, followed very shortly by a peak in the polymerization rate. Beyond the peak, the rate begins to drop sharply and the polymer beads become less porous as the free monomer is absorbed into the polymer and polymerizes. Such change in the particle character, both in terms of porosity and particle size distribution, is disadvantageous to the manufacturer in terms of reduced performance and economy of production. Thus, the granulated porous structure is desired for enhanced plasticizer uptake to form dry blends for various extruding or calendaring operations. In order to avoid such adverse effects, the manufacturer will terminate the polymerization reaction prior to complete monomer conversion. The experience of the manufacturer will best determine the point at which polymerization is terminated to give high quality polymer, although 70 to 90% conversion reflects a general termination point.

Components b) and c) are preferably added at this stage of PVC manufacture. (Anspruch 13)

5 Particularly preferred is a process wherein the polymerization is a suspension polymerization and the components b) and c) are added as an emulsion to the slurry towards the end of the polymerization reaction. (Anspruch 14)

10 Yet a further aspect of the invention is the use of a sterically hindered phenolic antioxidant with a melting point of more than 20° C together with a thioether or thioether-ester with a melting point of more than 20° C according to claim 1 for the thermal stabilization of aqueous suspensions or emulsions of halogen containing polymers. (Anspruch 14)

The following examples illustrate the invention.

15 General polymerization procedure:

A standard PVC polymerization reaction is carried out according to the suspension process in batch operation. A double jacketed pressure reactor of a volume of 5000 ml is operated at a temperature of 57 °C, and a stirrer velocity of 1000 rpm. The pressure and the temperature in the reactor during the reaction are recorded.

The following recipe is added into the reactor:

1000 ml demineralized water, degassed

375 g vinyl chloride monomer

1500 mg polyvinyl alcohol, suspending agent

25 0,1 mol-% (based on vinyl chloride monomer) of initiator di-2-ethylhexylperoxodicarbonate, 75% in isodecane (Luperox 233M®, supplier: Atofina)

30 300 ppm (based on the weight of vinyl chloride monomer) of the additives given in table 1 are added at the beginning of the pressure drop (after approximately 3h reaction time). After a further reaction time of 1 hour, the reactor is degassed, and the polymer obtained is isolated by filtration. The obtained crude polymer is washed with water, filtered, washed with ethanol, and dried under vacuum at 40°C, until the weight remains constant. Yield: 88%.

Evaluation of the thermal stability of PVC resin:

- 35 -

The heat stability of PVC resins is evaluated by measuring the dehydrochlorination reaction using a "763 PVC Thermomat®" (supplier Metrohm AG, CH 9101 Herisau, Switzerland). The amount of hydrochloric acid released from the PVC resin is a measure for its thermal instability. The amount of hydrochloric acid is quantified by dissolving it in water, and measuring the conductivity of the solution (see Table 1). The longer it takes to reach a certain level of conductivity, the more stable is the resin.

Table 1:

Example	additives	dosage form of additives	additive concentration (active)	PVC resin K-value	Thermal stability of PVC resin*
1 comparative	Irganox 245 DW®	suspension	300 ppm	K-67	20 minutes
2 comparative	Irganox 1141 EM®	emulsion	300 ppm	K-67	24 minutes
3 inventive	Compound 1/DLTDP 1:1	emulsion	300 ppm	K-67	29 minutes

* Test: dehydrochlorination at 180°C, air (minutes to reach a conductivity of 60 microsiemens/cm)

Preparation of PVC compounds and evaluation of their thermal stability:

The heat stability of PVC compounds is measured by preparing mill blends based on the following recipe:

PVC Resin (S-PVC K-60)	300	g
Commercial Processing Aid	9	g
Wax	2	g
Calcium Stearate	2	g
Methyl tin mercaptide stabilizer	1	g

The blend is placed on a heated 2 roll mill at about 195°C for up to 15 minutes. Every 3 minutes material is removed from the mill and pressed into plaques. The color (Yellowness Index, YI according to DIN 6174) of the plaques is measured. The lower the YI, the better the thermal stability of the PVC compound (Table 2).

The results in Table 2 clearly indicate that the stabilization according to the instant invention also increases the stability during the compounding step.

Table 2

5 Thermal stability (color) of PVC compound

Yellowness Index after minutes on roll mill at 195° C					
Stabilisers	3 minutes	6 minutes	9 minutes	12 minutes	15 minutes
300 ppm Irganox 245®	2.4	5.8	9.4	13.9	21.6
150 ppm compound 1 150 ppm DLTDP	-1.2	1.7	5.1	9.2	16.2
